1 Recurrence Relations and Analysis of Algorithms

1.1 Recurrence Relations

Insertion sort: let $M(n)$ be the comparisons required to sort a list of size n

Analysis: note that $M(1) = 0$ and $M(n) = M(n-1) + n$ for $n > 1$

- (i) $M(n) = M(n-1) + n$
- (ii) $M(n) = M(n-2) + n + (n-1) \dots$
- (iii) $M(n) = M(n-k) + n + (n-1) + \dots + (n-k+1)$
- (iv) Let $k = n-1$, $M(n) = M(1) + n(n-1+1) + \sum_{i=1}^{n-1} i$
- (v) $M(n) = 0 + n + (n-1)(n-2)/2 \approx n^2/2$

Merge sort: let $M(n)$ be the comparison required to sort a list of size n

Analysis: for simplicity, consider only n such that $n = 2^a$ for some integer a

Note that $M(1) = 0$ and $M(n) = M(n/2) + n$ for $n > 1$

- (i) $M(n) = M(n/2) +$

Recursive linear selection algorithm: given x_1, x_2, \dots, x_n distinct keys, find x_k (i.e. the k th smallest element) without using sorting

Note: the rank of an element (i.e. the number of keys greater than it) can be found in linear time

Linear selection algorithm is as follows:

- (i) Remove keys of known rank, to make $n = 5 \pmod{10}$
- (ii) Divide elements into groups of 5, denoted $S[i]$ for i from 1 to $n/5$
- (iii) Recursively find the median of each group, denoted $x[i]$
- (iv) Let M^* be the median of the set $x[i]$ for i from 1 to $n/5$
- (v) Divide keys into groups of keys less than (call this L), equal to, or greater than (call this R) M^*
- (vi) Recursively process one of L or R

Analysis: Note that steps 1, 2, and 5 are $O(n)$, so the number of computations for this algorithm, $T(n) = T(n/5) + T(7n/10) + O(n)$

Guessing and proving: supposed that $T(n) = O(n)$, which can be proven via strong induction, i.e. $T(n) < An$ for some constant A for all n

Recall that strong induction relies on proving two claims:

- (i) The statement holds for all $n \geq 1$, $\forall n \leq n_0$ (base case)
- (ii) If the statement holds for all $i < n$, it holds for n

Proof of second part of strong inductive proof:

- (i) Suppose that $T(n) = O(n)$ for $i < n$
- (ii) We seek an A such that $A(n/5) + A(7n/10) + cn \leq An$
- (iii) Thus, $A \geq 10c$ is sufficient for this part

Proof of first part of strong inductive proof: need A such that $n(n-1)/2 \leq An$ for $1 \leq n \leq 10$

So $A \geq 9/10$ is sufficient for this part

Conclusion: $A = \max\{9/2, 10c\}$ will suffice to show that $T(n) = O(n)$

Recursive quadratic algorithm: find closest pair of points

- i (Supposing that $n = 2^k$) into 2 equal groups, denoted L and R
- ii Recursively find the closest pair in L and R
- iii Report closest pair from testing elements of L against elements of R
- iv Report best pair out of those from steps (ii) and (iii)

Analysis: $T(n) = 2(T/n) + O(n^2)$ for $n = 2^k \geq 4$, $T(2) = 1$

The $O(n^2)$ in the recursive case comes from step (iii)

Consider the recursion tree, which is full binary tree: at the first level, the problem size is $n, n/2, n/4, \dots$ at the first, second, third, etc. levels. Thus, the number of computations required is n^2 at the first level, $2(n/2)^2 = n^2/2$ at the second level, $2(n/4)^2 = n^2/4$ at the third, etc.

Thus, the maximum number of computations is $\sum_{k=1}^{\infty} n^2/2^k = 2n^2$, thus $T(n) = O(n^2)$
